Project topic: Appointment Tracking

Introduction to Appointify:

The program I created called “Appointify”. It’s simply appointment creating and tracking program. It can be used for clinics, private lessons, barber shops… I mean everywhere that uses appointment system.

As an admin, admins can assign appointments to users or cancel the appointments. And as a user, people can follow their appointments or reschedule them. Program has some tables that appointments on it as well.

How users can use it:

New users got to register first, that means you got to fill the personel information properly (mail, phone number, gender). We have some rules here, user must create a unique username and its must be around 3-10 chars. This is just an example we got other rules for mail, phone number, password too.

And then user logins and sees the user panel which it’s have information about current appointment. Each user panel specialized for the user. In panel user can cancel the appointment or reschedule it. In reschedule panel it has huge table that if any appointment exists at an hour, it has a X appears in it. Reschedule means old appointment gets cancelled and new one is created.

How admins can use it:

New admins can register with access code which is unique to every company. After login, admin panel comes up. Admin panel has huge table that shows appointments in sophisticated hour. User’s username appears in it.

Admin panel also has four different tabs which are {add app, cancel app, user list, admin list}.

In add app tab, admin chooses a user, day, hour and types a description then appointment had been created. If you refresh it appears on the table. In cancel app tab, admin chooses a user, user's appointment's information will be shown in the list and admin can cancel it there.

In user list tab, you can see all the users and can delete them. When a user being deleted if it has a current app it'll be deleted too. In admin list tab, all admins are shown.

In the top left of the panel we have Get Information section which we can see all the information of the users (admins included) by that.

How I done it:

When I was creating the program I used all the component and tools that I supposed to include to the program. Here they are:

14x Total .java files

10x Frames

5x Database Tables

The ones with I struggled to use:

1x Menu item check box

1x Popup menu

1x Spinner

1x Split pane

What did I learn:

I learned bunch of stuff during coding the program. And now I have a good understanding of SQL. I'm glad I have done the program just like in my mind.
